# Study on Response Loss under Linear Regression Model 

Limin Song<br>School of Mathematics and Statistics, Shandong University of Technology, Zibo, Shandong, China

#### Abstract

This paper mainly studies the problem of missing response under the linear regression model, systematically summarizes the development situation, and introduces the research background and significance of missing response variables. The following focus: the first step is to build a missing model of linear regression response.In the second step, the two aspects of mean interpolation and observation data estimation are studied in detail respectively, and the specific mathematical formulas are given. In the third step, the estimate of regression coefficient, mean, distribution function, quantile under "complete sample" based on missing value and based on part number.

Keywords: Linear Regression, Missing Response Variable, Mean Interpolation, Estimation Of Observation Data

## I. INTRODUCTION

In the process of daily research and learning, the absence of data is indispensable and inevitable. People usually think of using the traditional statistical analysis methods to compensate for the missing data, but due to the lack of data, these statistical methods cannot be completed smoothly. Now the question is transformed into how to deal with these missing data, so that we can make the statistical method continue, which has also become a hot topic, and has aroused the attention and research of many experts and scholars. Through this paper, we can accurately find the response missing model, and quickly solve the missing problem with mean interpolation and observation data estimation, and give the estimation of regression coefficient, mean, distribution function and quantile in three cases, so as to achieve the expected research purpose.

## II. CONSTRUCTION OF THE RESPONSE MISSING MODEL

Consider the linear model as follows

$$
Y=X \beta+\varepsilon \in R^{n \times 1}
$$

a $\quad \mathrm{m} \quad$ o $\quad \mathrm{n} \quad \mathrm{g} \quad, \quad X=\left(X_{1}, X_{2}, \ldots, X_{p}\right) \in R^{n \times p}$
$\beta=\left(\beta_{1}, \beta_{2}, \ldots, \beta_{p}\right)^{T} \in R^{p \times 1}$ is an unknown parameter vec
tor, $Y$ is response variable, $\varepsilon=\left(\varepsilon_{1}, \varepsilon_{2}, \ldots, \varepsilon_{n}\right)^{T} \in R^{n \times 1}$,error
sequence $\{\varepsilon\}$ meet the independent and identical distributio
n, and $E(\varepsilon \mid X)=0,0<\sigma^{2}=\operatorname{Var} \varepsilon<\infty, \operatorname{Var}(\varepsilon \mid X)=\delta^{2}$.

Incomplete samples with an independent and identical dist ribution are assumed $\left\{\left(\mathrm{X}_{\mathrm{i}}, \mathrm{Y}_{\mathrm{i}}, \delta_{\mathrm{i}}\right), 1 \leq \mathrm{i} \leq \mathrm{n}\right\}$ the corresponding
whole population, among $\left\{X_{\mathrm{i}}, 1 \leq \mathrm{i} \leq \mathrm{n}\right\}$ can be all observe d, $\left\{Y_{\mathrm{i}}, 1 \leq \mathrm{i} \leq \mathrm{n}\right\}$ is missing, $\delta_{\mathrm{i}}$ is indicating the $Y_{\mathrm{i}}$ missing v ariables, is a $1 \times n$ vector, i. e

$$
\delta_{\mathrm{i}}=\left\{\begin{array}{c}
0, \text { if } \quad Y_{i} \quad \text { is mis } \sin g \\
1, \text { if } \quad Y_{i} \quad \text { is not missin } g
\end{array} .\right.
$$

Now use $(X, Y, \delta)$ instead $\left\{\left(X_{i}, Y_{i}, \delta_{i}\right), 1 \leq i \leq n\right\}$ the corres ponding whole population. Therefore, it is assumed that $\left\{Y_{i}\right\}$ meet the MAR deletion mechanism, even $P(\delta=1 \mid X, Y)=P(\delta=1 \mid X)=P(X)$, that is, under the given $X, Y$ and $\delta$ independent from the conditions.

For convenience, we now introduce a notation:
$\mathrm{r}=\sum_{\mathrm{i}=1}^{\mathrm{n}} \delta_{\mathrm{i}}, \mathrm{used}$ to represent the number of cells without missing data;
$\mathrm{m}=\mathrm{n}-\mathrm{r}$,used to represent the number of cells presence of missing data;
$\mathrm{s}_{\mathrm{r}}=\left\{\mathrm{i}: \delta_{\mathrm{i}}=1, \mathrm{i}=1, \ldots \ldots, \mathrm{n}\right\}$, used to represent the cell set without missing data;
$\mathrm{s}_{\mathrm{m}}=\left\{\mathrm{i}: \delta_{\mathrm{i}}=0, \mathrm{i}=1, \ldots \ldots, \mathrm{n}\right\}$, used to represent the set of t he cells with missing data.

## III. MEAN INTERPOLATION

Mean interpolation method is to replace the unobserved missing data with the mean of the observed data, which is more applicable when the observed data variables obey or approximate to the normal distribution. $Y=\left\{Y_{o b s}, Y_{m i s}\right\}, Y_{o b s}$ is the observed data in the data matrix $Y, Y_{m i s}$ is the missing part in the $Y, n=n^{O B}+n^{N A}$,the single mean interpolation method is to average all the observed data and interpolate the missing data to obtain the unique mean as the interpolation value, namely $\overline{y_{1}}$,

International Journal of Trend in Research and Development, Volume 9(4), ISSN: 2394-9333 www.ijtrd.com

$$
\overline{y_{1}}=\frac{\sum_{i=1}^{n} \delta_{i} y_{i}}{n^{O B}}
$$

The obtained population mean is estimated as:

$$
\hat{\bar{Y}}=\frac{1}{n} \sum_{i=1}^{n}\left[\delta_{i} y_{i}+\left(1-\delta_{i}\right) \bar{y}_{1}\right]=\frac{n^{O B}}{n} \bar{y}_{1}+\frac{n-n^{O B}}{n} \bar{y}_{1}=\bar{y}_{1}
$$

It can be seen that the mean of the observed data is also an interpolated population mean estimate. $s^{2}$ is the varianc e of the overall data, $s_{1}^{2}$ is the variance of the observed da ta, $\bar{y}$ is the mean of the data, $\bar{y}_{1}$ is the mean value of the observed data, $y_{j}$ is the value of the $j$ th observation data, $y_{j}^{\prime}$ is the jth missing value, therefore

$$
s^{2}=\sum_{i=1}^{n} \frac{\left(y_{i}-\bar{y}\right)^{2}}{n-1}=\frac{\left[\sum_{i=1}^{n}\left(y_{j}-\bar{y}_{1}\right)^{2}+\sum_{i=1}^{n}\left(y_{j}^{\prime}-\bar{y}_{1}\right)^{2}\right]}{n-1} .
$$

Using the mean value of the observed data with $\bar{y}_{1}$, instead of the unobserved $y_{j}$, therefore

$$
s^{2}=\sum_{i=1}^{n} \frac{\left(y_{i}-\bar{y}_{1}\right)^{2}}{n-1}=\frac{s_{1}^{2}\left(n^{O B}-1\right)}{n-1} .
$$

## IV. OBSERVE THE DATA FOR THE ESTIMATION (OE)

First, it can be obtained by the projection $\left\{Y_{o b s}, Y_{m i s}\right\}$, acco rding to $X_{\text {obs }}$ obtain $\hat{\beta}$,i.e. $\hat{\beta}=\left(X_{\text {obs }}^{T} X_{\text {obs }}\right)^{-1} X_{\text {obs }}^{T} Y_{\mathrm{obs}}$. Then, based on complete observations $\left(X_{i}, Y_{i}\right)$ for $\beta$ weighted le ast squares (WLS) estimation, $i \in s_{r}$.

$$
\hat{\beta}_{r}=\left(\sum_{i=1}^{n} \frac{\delta_{i} \tilde{X}_{i}^{\prime} \tilde{X}_{i}}{v_{0}^{2}\left(X_{i}\right)}\right)^{-1} \sum_{i=1}^{n} \frac{\delta_{i} \tilde{X}_{i} Y_{i}}{v_{0}^{2}\left(X_{i}\right)}
$$

Among $v_{0}(X)$ is a strictly positive, known function.

And then, by calculation $\hat{Y}_{m i s}$,i.e. $\hat{Y}_{m i s}=X_{m i s} \hat{\beta}$.Using $\hat{Y}_{m i s}$ to fill $Y_{m i s}$, then get $\left\{Y_{o b s}, \hat{Y}_{m i s}\right\} . \hat{Y}$ can be obtained a fter the expansion.

Making estimates under a "complete sample" with missing values, using the observed sample data for the pairs of $\left\{\left(\mathrm{X}_{\mathrm{i}}, \mathrm{Y}_{\mathrm{i}}\right), \mathrm{i} \in \mathrm{s}_{\mathrm{r}}\right\}$, given the estimates of the regression coeffi cients, mean, distribution function, quantile, i.e.,

$$
\hat{\beta}_{n 1}=\left(\sum_{i=1}^{n} \delta_{i} X_{i}^{\prime} X_{i}\right)^{-1}\left(\sum_{i=1}^{n} \delta_{i} X_{i}^{\prime} Y_{i}\right)
$$

$$
\bar{Y}_{n 1}=\frac{1}{r} \sum_{i=1}^{n} \delta_{i} Y_{i}
$$

$$
\hat{F}_{n 1}(Y)=\frac{1}{r} \sum_{i=1}^{n}\left\{\delta_{i} I\left(Y_{i} \leq Y\right)\right\}
$$

$$
\hat{\theta}_{q 1}=\inf \left\{\hat{F}_{n 1}(u) \geq q\right\}=\hat{F}_{n 1}^{-1}(q)
$$

## V. ESTIMATES BASED ON THE FIXED COMPLEMENT UNDER THE MISSING RESPONSE

Using fixed complement methods to fill in the missing re sponse variables, when $Y_{i}$ is missing, it is complemented $w$ ith its predicted value, that is $Y_{i 1}^{*}=X_{i} \hat{\beta}_{n 1}, i \in S_{m}$, is a $p \times n$ matrix , as $Y_{i}, i \in s_{m}$ fill the value. After making up, $\tilde{Y}_{i 1}=\delta_{i} Y_{i}+\left(1-\delta_{i}\right) Y_{i 1}^{*}, i=1, \ldots, n$, is a numerical value. Therefore, based on the estimation of the regression coef ficient, mean, distribution function and quantile after fixed complement, that is,

$$
\begin{gathered}
\hat{\beta}_{n 2}=\left(\sum_{i=1}^{n} X_{i}^{\prime} X_{i}\right)^{-1}\left(\sum_{i=1}^{n} X_{i}^{\prime} \tilde{Y}_{i 1}\right) \\
\bar{Y}_{n 2}=\frac{1}{n} \sum_{i=1}^{n} \tilde{Y}_{i 1}
\end{gathered}
$$

$$
\begin{gathered}
\hat{F}_{n 2}(Y)=\frac{1}{n} \sum_{i=1}^{n}\left\{\delta_{i} I\left(Y_{i} \leq Y\right)+\left(1-\delta_{i}\right) I\left(Y_{i 1}^{*} \leq Y\right)\right\} \\
\hat{\theta}_{q 2}=\inf \left\{\hat{F}_{n 2}(u) \geq q\right\}=\hat{F}_{n 2}^{-1}(q)
\end{gathered}
$$

## VI. ESTIMATES FILLED BASED ON LINEAR REGRESSION FILLING WITH MISSING RESPONSE

Using the stochastic method, and learn from the part num ber linear regression filling method, that is, to use $Y_{i 2}^{*}=X_{i} \hat{\beta}_{n 1}+\varepsilon_{i}^{*}, i \in s_{m}$, is a $p \times n$ matrix, as $Y_{i}, i \in s_{m}$
 $\varepsilon_{i}^{*}=J^{-1} \sum_{i=1}^{J} \varepsilon_{i l}^{*}, J \geq 1,\left\{\varepsilon_{i l}^{*}, l=1, \ldots, J\right\} \quad$ i s $\quad$ from $\left\{Y_{j}-X_{j}^{\prime} \hat{\beta}_{n 1}, j \in s_{r}\right\}$ selected independently and repeatedly $J \quad \mathrm{sample}$. After making up, $\tilde{Y}_{i 2}=\delta_{i} Y_{i}+\left(1-\delta_{i}\right) Y_{i 2}^{*}, i=1, \ldots, n$,is a numerical value.

Therefore, the regression coefficient, mean, distribution fun ction and quantile based on random complement, that is,

$$
\hat{\beta}_{n 3}=\left(\sum_{i=1}^{n} X_{i}^{\prime} X_{i}\right)^{-1}\left(\sum_{i=1}^{n} X_{i}^{\prime} \tilde{Y}_{i 2}\right)
$$

$$
\begin{gathered}
\bar{Y}_{n 3}=\frac{1}{n} \sum_{i=1}^{n} \tilde{Y}_{i 2}, \\
\hat{F}_{n 3}(Y)=\frac{1}{n} \sum_{i=1}^{n}\left\{\begin{array}{l}
\delta_{i} I\left(Y_{i} \leq Y\right)+ \\
\left(1-\delta_{i}\right) J^{-1} \sum_{l=1}^{J} I\left(X_{i} \hat{\beta}_{n 1}+\varepsilon_{i l}^{*} \leq Y\right)
\end{array}\right\}, \\
\hat{\theta}_{q 3}=\inf \left\{\hat{F}_{n 3}(u) \geq q\right\}=\hat{F}_{n 3}^{-1}(q) .
\end{gathered}
$$
